

Functional Components

This document describes the main functional components of the `apply-doc-standards` tool.

Core Components

Application

The `Application` class is the main entry point of the application. It is responsible for:

- Parsing the command-line arguments.
- Loading the configuration.
- Orchestrating the file scanning and processing.
- Displaying the results to the user.

Public API:

- `run(array $argv): int`: Runs the application.

Utility Components

ConfigManager

The `ConfigManager` class is responsible for managing the configuration of the application. It can load configuration from a file and provides methods to get and set configuration values.

Public API:

- `loadFromFile(string $filePath): void`: Loads configuration from a file.
- `get(string $key, $default = null)`: Gets a configuration value.
- `set(string $key, $value): void`: Sets a configuration value.
- `isDryRun(): bool`: Checks if the application is in dry-run mode.
- `shouldForce(): bool`: Checks if the processing should be forced.

FileScanner

The `FileScanner` class is responsible for scanning for files to be processed. It can scan a directory recursively and filter files by extension.

Public API:

- `scanDirectory(string $directory, bool $recursive): array`: Scans a directory for files.

DocumentationProcessor

The **DocumentationProcessor** class is responsible for processing the documentation files. It applies the documentation standards to the files, including:

- Adding an anchored document title.
- Creating or repositioning the Table of Contents.
- Adding an introduction section.
- Numbering the content sections.
- Adding a navigation footer.

Public API:

- `processFile(string $filePath, array $options): array`: Processes a single file.
